

Against Breast Cancer

[DOWNLOAD HERE](#)

As I stated in the introduction, breast cancer is a bunch of cells in the breast that become abnormal for some reason. Scientists suspect that some forms of bacteria get into the cells and cause mutation. The mutated cells can attack other normal cells and cause them to become mutated. Some cells end up getting destroyed. When enough cells are changed in this manner, cancer develops. Sometimes a small amount of mutated cells end up becoming cancerous. This is why cancer often starts small, in a certain section of the breast and spreads from there. If the cancer is not stopped or controlled, it could end up spreading beyond the breast and end up in other areas of the body. This is when it becomes an absolute necessity to find a cure and quickly.
